

GREECO

Territorial Potentials for a Greener Economy

Applied Research 2013/1/20

Final Report | Version 14/03/2014

Scientific Report

Vol. 2.5. Assessing regional green economic performance

This report presents the final results of an Applied Research Project conducted within the framework of the ESPON 2013 Programme, partly financed by the European Regional Development Fund.

The partnership behind the ESPON Programme consists of the EU Commission and the Member States of the EU27, plus Iceland, Liechtenstein, Norway and Switzerland. Each partner is represented in the ESPON Monitoring Committee.

This report does not necessarily reflect the opinion of the members of the Monitoring Committee.

Information on the ESPON Programme and projects can be found on www.espon.eu

The web site provides the possibility to download and examine the most recent documents produced by finalised and ongoing ESPON projects.

This basic report exists only in an electronic version.

1. Introduction

The analysis of the regional green economic performance aims to shed light on how the regions in Europe are doing from a green economic perspective. The analysis is based on GREECO's conceptualisation and operationalisation of the green economy and the indicator definition and collection. The objective of the analysis is to provide a quantitative profile of the green economy at the regional level in Europe, i.e. it was attempted to give an answer to the question on how far we have already progressed towards a green economy in different parts of Europe. However, this objective can only be partly achieved due to fragmentation, gaps or non-availability of the necessary data.

The green economy is a policy-oriented concept that can be characterised as an operationalisation of *sustainable development* (see GREECO Main Report for further detail). This idea is implicit in near all definitions of the green economy concept. All of them build on the three traditional spheres included in the definition of Sustainable Development, namely environmental, social and economic.

In GREECO's conceptualisation, these three traditional spheres were extended to include two additional dimensions. The first one is the *econosphere*, where the key structural elements of economic transformation are shaped against the environmental background. The econosphere takes account of the extent to which decoupling of economic growth and social well-being from energy consumption and resource depletion is taking place. The second one is the *territorial sphere*. Its inclusion rests on the idea that territorial equilibrium and cohesion are requisites for a genuine socio-economic development to take place. The green economy, as the operationalisation of sustainability, should contribute to strengthen the territorial balance too.

GREECO's simplified definition of the green economy presents all these ideas in a more structured way. "The green economy can be defined as the socio-economic development that takes place vis-à-vis a more sustainable use of natural resources, preservation of environmental capital and fewer environmental risks, while at the same time enhancing regional competitiveness and cohesion over the long term" (GREECO Main Report).

Against this theoretical backdrop, the conceptual framework of GREECO has taken account of all green economic dimensions included in previous definitions. A graphical representation of these conceptual elements is presented in Figure 1.

Basic approach

The analysis of green economy regional performance is based on two different but interrelated strands of research within GREECO, a bottom-up approach and a top-down approach.

- The bottom-up approach is built on the GREECO analyses of economic sectors. For each of the sectors under study, one key indicator has been selected at the end of the sector analysis task. The main requirements for those indicators are that they have a certain representativeness for the sector and that they are available at regional level.
- The top-down approach is more comprehensive across individual sectors. This part of the performance analysis is based on the five spheres of the green economy" as classified by GREECO. For each of the spheres, environment, society, diverse territories, the economy and its production and consumption aspects and the econosphere, quantitative profiles of green economic performance are given.

Figure 1. GREECO conceptual framework (Source: GREECO Main Report).

The different indicators in the two strands of analysis are presented and analysed one by one, i.e. the regional green economic performance is analysed by economic sector in the first part and by green economy spheres in the second.

Different approaches have been explored to aggregate from individual indicators to more abstract levels of analysis. A multicriteria evaluation technique has turned out to be most suitable for the aggregation of individual indicators. The output from this step is a tentative assessment of regional green economic performance across Europe. Finally, green economic performance is related to overall regional economic performance.

One of the theoretical aspects when considering the question of the regional level of the green economic performance is whether there is a knowledge gain when going down to lower spatial levels with the analysis. Probably, many aspects of the green economy would get already a value added in spatial terms, if NUTS-1 or even NUTS-0 data would be analysed. The topic of the green economy is so immature in every respect that an analysis at such aggregate spatial levels would bring huge new knowledge in spatial terms. This is supported by the fact that policies fostering the green economy are developed very often at national level or depending on the level of subsidiarity in different countries at NUTS-1 level, but not below. However, more spatial detail is requested in ESPON and probably necessary for many aspects of the green economic performance. GREECO tries to go as deep as feasible in spatial terms. In GREECO, the analysis is first done at the spatial levels at which the data is available. This ranges from NUTS-0 down to NUTS-3. Only for the integrated assessment of the regional green economic performance, data were transferred to a common territorial reference framework, i.e. NUTS-2. This harmonisation includes also the simplest form of data disaggregation, i.e. the use of NUTS-0 or NUTS-1 data (shares, indices etc.) at NUTS-2 level thus simply assuming that there is no spatial variation.

2. From green economy concept to performance indicators

The task of measuring regional green economic performance is closely related to the state of the five spheres of the green economy, namely the environmental sphere, the social sphere, the territorial sphere, the economic sphere and the econosphere. This section first reviews existing concepts from international sources in which an explicit indicator system for measuring the green economy was developed. It then proposes two sets of headline indicators by which GREECO addresses the question of regional green economic performance.

Existing concepts to measure the Green Economy

The OECD (2011) has proposed a concept for measuring the progress towards green growth which closely follows their working definition: "Green growth is about fostering economic growth and development while ensuring that the natural assets continue to provide the resources and environmental services on which our well-being relies. To do this it must catalyse investment and innovation which will underpin sustained growth and give rise to new economic opportunities." (OECD 2011, p. 16). The indicator system is considered as being pragmatic: "green growth indicators are seen as markers or milestones on a path of greening growth and of seizing new economic opportunities" (ibid.)

The indicator system is besides some background indicators organised in four main themes (in italic) reflecting the elements of the working definition of green economy:

- *Environmental and resource productivity*: CO₂ productivity, energy productivity, material productivity, water productivity, multi-factor productivity,
- *Natural asset base*: freshwater resources, forest resources, fish resources, mineral resources, land resources, soil resources, wildlife resources,
- *Environmental quality of life*: environmentally induced health problems and related costs, exposure to natural or industrial risks and related economic losses, access to sewage treatment and drinking water,
- *Economic opportunities and policy responses*: R&D of importance to GG, patents of importance to GG, environmental related innovation, production of environmental goods and services, international financial flows of importance to GG, environmentally related taxation, energy pricing, water pricing and cost recovery.

UNEP (2012) in a recent working paper has proposed an indicator system for measuring progress towards a green economy by closely following their definition of green economy that has to deliver improved human well-being and social equity while significantly reducing environmental risks and ecological scarcities (see also Section 3.1). Based on UNEP's view that green economy is not as a goal as such but as a tool to achieve sustainable development and poverty reduction, the proposed indicator system is only partly focussed on the state of the green economy which is of interest here, but mostly on how green economy as an approach is applied in policymaking processes. However, the proposed indicator lists have the character of illustrative examples rather than that of a fixed indicator system.

For the environment, the following issues (in italic) and related indicators are given:

- *Climate change*: carbon emissions, renewable energy share, energy consumption per capita,
- *Ecosystem management*: forestland, water stress, land and maritime

- conservation area,
- *Resource efficiency*: energy productivity, material productivity, water productivity, CO₂ productivity,
- *Chemicals and waste management*: waste collection, waste recycling and reuse, waste generation or landfill area.

For policy interventions the following policies (in italic) and related indicators are given:

- *Green investment*: R&D investment, EGGS investment,
- *Fiscal reform*: Fossil fuel, water and fishery subsidies, fossil fuel taxation, renewable energy incentive,
- *Pricing*: Carbon price: value of biodiversity, value of ecosystem services,
- *Green procurement*: expenditure in sustainable procurement, CO₂ and material productivity of government operations,
- *Training*: training expenditure, number of people trained.

Finally, indicators for issues (in italic) of well-being and equity are given:

- *Employment*: construction, operation and management, Gini coefficient,
- *EGSS performance*: value added, employment, CO₂ and material productivity,
- *Total wealth*: Value of natural resource stocks, net annual value addition/removed, literacy rate,
- *Access to resources*: access to modern energy, access to water, access to sanitation, access to health care,
- *Health*: number of people hospitalised due to air pollution, road traffic fatalities.

A somewhat different approach has been introduced by the Directorate General for Economic and Financial Affairs (ECFIN) of the European Commission. The iGrowGreen assessment framework is set up to "systematically compares EU Member States' environmental performance with macroeconomic and fiscal implications across 4 green policy domains and 9 policy areas, taking account of performance in levels and changes for more than 70 indicators" (ECFIN – GD Economic and Financial Affairs of the European Commission 2012). iGrowGreen contains quantitative scores for the 27 Member States, together with the underlying data and computations. It covers four domains, each reflecting a key link from environmental performance to macroeconomic and fiscal considerations:

- *Environmental tax reforms and fiscal consolidation*: indicators on the revenues side and the expenditure side,
- *Strengthening market functioning and competitiveness*: indicators on clean and efficient energy sector, sustainable use of resources, markets for green products,
- *Boosting new sources of growth*: indicators on green human capital and green technological progress
- *Climate change and biodiversity*: indicators on climate change and biodiversity.

The difference to the other indicator systems is that in iGrowGreen not only the individual indicators can be used, but that the main feature is the option to get one synthetic score per country for each of the four topics above. The weighting system is made transparent for the user.

Regional green economic performance measuring via headline indicators

The conclusions from the three examples on green economy or green growth indicator

systems developed by international organisations are

- that indicator systems on green economy have to have a close relationship to the theoretical conceptualisation they are embedded in;
- that an indicator system on green economy should be organised in a hierarchical way, i.e. with major topics supported by headline indicators and a wider set of indicators in the background;
- that the indicator systems should deal with a wider range of topics than with the economy in a narrow sense only by addressing also aspects such as human well-being, environmental aspects and in particular all kinds of resource efficiency;
- that it is reasonable to work with indicators on green economy side by side, but also that it might be meaningful to aggregate indicators to synthetic indices;
- that none of the indicator systems explicitly addresses territorial differentiation and that none of the indicator systems goes spatially below the country level.

Against this background, the indicator system for measuring the regional green economic performance in GREECO is closely related to the conceptual base of the project. On the one hand, there is a strand of indicators for green economy directly derived from the bottom-up approach, i.e. the sectoral analysis. The second set of indicators is more comprehensive, i.e. does not necessarily address individual economic sectors, and is strictly derived from the five spheres of green economy as developed in GREECO.

Along these lines, both indicator sets on regional green economic performance of GREECO are organised along major topics which are either the economic sectors or the green economy spheres. The economic sectors are each represented by one headline indicator. The five spheres of the green economy are decomposed each in some components which are represented by selected headline indicators and which again might be backed up by a series of corresponding indicators.

Table 1 presents the headline indicators for the bottom-up derived regional performance indicator set, i.e. the economic sectors analysed in GREECO. The headline indicators were proposed by the authors of the sectoral studies.

Economic Sector	Headline indicator
Agriculture	Organic area
Building and construction	Energy consumption in residential buildings
Energy production	Renewable energy
Green research and eco-innovation	Eco-innovation scoreboard
Manufacturing	Environmental protection expenditure
Tourism	Tourist overnight stay density
Transport	Motorisation rate
Waste management	Waste recycling
Water management	Waste water treatment

Table 1 Headline indicators for regional green economic performance of economic sectors

The indicators for the regional green economic performance based on the GREECO conceptualisation of the green economy are organised along the five spheres defined in GREECO. Table 2 lists the spheres, their components and headline indicators.

- For the *environmental sphere*, the source function and the sink function are the two main components to be addressed. The first headline indicator is a comprehensive indicator developed by the EEA on environmental and natural assets, which describes what the current performance of the environment is in terms of availability of open space, biodiversity etc. The second headline indicator reflects how much the sink function of the environment is being exploited, an indicator of air pollution is used for this.
- For the *social sphere*, the first indicator reflects the impact of the economy on the well-being of population; life expectancy is used as a proxy for health. The topic of environmental risk can be expressed by the exposure of population to environmental risks such as air pollution.
- For the *territorial sphere*, the concept of territorial keys developed in the background document of the Polish Presidency (Böhme et al. 2011) are used. One important territorial key for green economy is "Territorial capacities/endowment assets" for which one of the indicators of the document referred to above can be directly used, i.e. renewable energy production. A second indicator on land take per GDP unit can be seen as a proxy for the "Wise management of cultural and natural assets" or, more generally, as a proxy of "Spatial efficiency".
- For the *economic sphere*, GREECO's intention was to address the "greenness of economic activities" as far as possible. How far economic supply can be considered as green is reflected in a proxy indicator expressing the share of SMEs that offer green products or green services. How far green technology is being developed by the regional economies is reflected in the number of green patents submitted to the European Patent Office (EPO). This indicator can also be considered a green economy driver, as it is strongly related to the green technological development of a given region and thus with its future capacity for green growth.
- The *econosphere* is covered by environmental and resource productivity indicators. The headline indicator are energy productivity and CO2 productivity, i.e. measuring how much GDP is produced by an energy or CO2 unit. .

The presentation and analysis of the green economy regional performance indicators as outlined above gives a comprehensive picture on Europe, its countries and its regions. This comprehensive picture allows depicting several aspects of green economy for different economic sectors and for the five spheres of green economy as defined in the GREECO concept. This is a value as such as it allows to illustrate which regions are strong or weak in what aspect.

However, this picture of the regional green economic performance picture is not a single picture but a picture with numerous components, i.e. a set of individual pictures. A direct assessment of the overall green economic performance of regions is not possible based on such a range of individual indicators. Therefore, different indicators were aggregated by multicriteria analysis techniques. This aggregation has first been done to the five spheres of the green economy defined in GREECO and eventually to one single indicator of regional green economic performance of European regions. It has to be stated that this is a very explorative task based on limited availability of appropriate data, i.e. the results can only be interpreted as a first tentative assessment of regional green economic performance.

Core feature of Green Economy	Component	Headline indicator
Environmental sphere	Source function	Environmental and natural assets (EEA)
	Sink function	Emission of air pollutants
Social sphere	Health	Life expectancy
	Environmental risk	Exposure to air pollution
Territorial sphere	Territorial capacity	Renewable energy production
	Spatial efficiency	Land take per GDP unit
Economic sphere	Green supply	Green products and services offered
	Green technology	Green patents
Econosphere	Energy productivity	GDP per energy unit
	CO2 Productivity	GDP per CO2 unit

Table 2 Headline indicators for regional green economic performance for green economy spheres.

3. Headline indicators for regional green economic performance of economic sectors

This section presents for each economic sector analysed in GREECO one headline indicator representing the regional green economic performance of that sector. The headline indicators were proposed by the authors of the sector studies.

Agriculture

The headline indicator is the share of the total utilised agricultural area (UAA) under organic farming (see Figure 2). This share was 3.7 % of UAA of EU-15 in 2002, up from only 1.8 % in 1998. In 2008 the share increased to 4.3%. Organic production accounted for 2 % of EU-15 total production of milk and beef in 2001, but less than 1 % of total production of cereals and potatoes. From the report "An analysis of the EU organic sector" it is evident that the organic sector is developing at a fast pace in the EU. At farm level the rates of growth are rather impressive. Areas have increased by 6.5% per year on average in the EU-27 in the period 2000-2008, animal numbers have increased by the range of 6.1- 22.2% annually in the EU-15 depending on species groups. And in 2008 the organic sector represents a total area of 7.7 million ha with almost 190 000 farms. Italy has been for a long period the Member State with the largest organic area, exceeding one million ha since the beginning of the 2000s. However it is out performed by Spain in 2008 which reached an impressive 1.1 million ha. Some of the "pioneers" in the sector such as Denmark, Finland, Sweden and Italy seem to have reached a plateau or display only slow growth. Among Southern EU, Greece, Spain and Portugal which have grown fast in the last years.

Looking at the share of organic production in each country gives another picture of which countries are developing this type of farming. In countries such as Switzerland, Austria Finland, Italy, Denmark and Sweden the share of organic land area is between 6 and 10%. As a contrast in countries growing fast and showing a large amount of hectares, there is still only a low share of land devoted to organic farming; e.g. in Spain (2.4%) and France (1.8%). In large agricultural countries like Greece and Poland the share of certified organic production was only 0.4% in 2004, showing a great potential to increase in the coming years. This has taken place in Greece, where in many regions the share is now up to 5-10%. In Poland the picture is the same as in 2004 with many regions still below a share of 1%. In many regions in Germany and Austria, the share is clearly above 10%.

Building and construction

The headline indicator for the building and construction sector is the energy consumption in residential buildings. Given the high correlation between total residential energy consumption and population density, coupled with the lack of correlation between regional population density and per capita energy consumption, a simple but effective indicator of regional performance of the sector has been developed. Europe-wide figures for this indicator are not available. Figure 3 shows for some countries with appropriate data that there can be substantial differences in regional performance within countries. For example, apart from Bulgaria and Italy at the low and high ends, we see an average difference of 45% between per capita residential energy consumption in the lowest region and highest regions.

Figure 2. Share of organic farming in total utilised agricultural area in 2007.

Figure 3. Energy consumption per capita in residential buildings 2009 (Source: GREECO Building and Construction Sector Study).

Energy production

The headline indicator for the energy sector is the amount of renewable energy produced. Figure 4 shows the share of renewable energy in gross final energy consumption for the EU member states. The figure clearly depicts the huge differences ranging from almost no current importance of renewable energies in countries such as the UK, the Netherlands or Belgium up to countries such as the Nordic countries, Latvia and Austria in which the share of renewable energy is already more than one third or even up to almost two thirds of final energy consumption.

The information in the figure provides also some indication of the progress towards the 2020 targets – showing countries such as Sweden, Estonia and Romania as seeming to be close to their targets while other countries have a long way to go. However, this very overarching view can be misleading. The recently published Renewable energy progress report COM(2013) 175 final is a key component of Energy 2020 and the RES directive as it serves to benchmark progress as the MS level. It mentions that the 2010 renewable energy shares of 20 Member States and the EU as a whole were at the level of or above 2010 commitments set out in their national plans and above the first interim target for 2011/2012.

Green research and eco-innovation

The headline indicator selected for the green research and eco-innovation sector is the so-called Eco-innovation Scorebord (ECO-IS) which is developed by the Eco-Innovation Observatory (EIO) an EU funded platform aimed at collecting and analysing eco-innovation information, across the EU. The Eco-IS is the first and only tool to evaluate and show eco-innovation performance across the 27 EU Member States in a systematic way. Eco-IS via its composite Eco-innovation index demonstrates the eco-innovation performance of a country compared with the EU average and with the EU top performers. The Eco-IS captures different aspects of eco-innovation in order to provide a holistic view of economic, environmental and social performance and hence, identify strengths and weakness of EU countries. The aim is to compare relative performance of Member States in key areas (dimensions) related to eco-innovation, including investments, company performance and economic and environmental outcomes. The Eco-IS ranks regions in four groups according to national overall eco-innovation performance (see Figure 5):

- EU Leaders (e.g. the Nordic countries, Ireland, Germany, Belgium, Spain or Slovenia)
- Good EI achievers (the UK, France, the Netherlands, Portugal, Italy, Austria and the Czech Republic,
- Average EI performers (Baltic States and south-eastern European countries)
- Countries catching up in EI (e.g. Poland, Slovakia or Greece).

Figure 4. Share of Renewable Energy in final energy consumption, 2010, compared to 2011/2012 interim targets and 2020 target for member states 2010 (Source: GREECO Energy Sector Study).

Figure 5. Overall eco-innovation performance in 2012. (Source: GREECO Eco-Innovation Sector Study based on Eco-IS 2012).

Manufacturing

The headline indicator chosen for the manufacturing sector is the environmental protection expenditure of that sector. Figure 6 shows data at national level; data at regional level are available only for very few countries (see Figure 7).

Figure 6. Environmental protection expenditure of manufacturing sector, 2008-2010 (Source: GREECO Manufacturing Sector Study based on Eurostat data (sbs_env_dom_r2))

Figure 7. Environmental protection expenditure of industry as a whole in 2008. (Source: GREECO Manufacturing Sector Study based on Eurostat ENV_AC_EXP4R2)

Tourism

The headline indicator for the tourism sector is the tourist overnight stay density which reflects the tourism pressure on the European regions (Figure 8). Tourism is highly unevenly distributed across Europe. Tourism is concentrated in the Mediterranean regions, in the Alpine regions as well as along the Atlantic and North Sea coasts and in several capital cities. Many factors influence this pattern including accessibility, costs, and the attractiveness of the different regions. However, tourism is often concentrated even further locally below the NUTS 2 or 3 level shown in the map (e.g. along the coasts). As such the map only provides a general overview of high-pressure regions in a broad European context.

In a sustainability perspective, this spatial concentration of high number of tourists has economic, environmental and social impacts in the affected regions. The economic impacts include that tourism provides income and employment in the affected regions. Tourism causes a range of direct and indirect environmental impacts and is at the same time highly dependent on high environmental quality (e.g. bathing water qualities, availability of drinking water, clean air etc.). Generally, the impacts increase with the number of tourists in a region but also the treatment systems available play a significant role in reducing these environmental pressures and reducing the environmental “foot print” from tourism (as well as from local households). The social impacts of tourism are also diverse and both positive and negative. Generally, the impacts increase with the number of tourists in a region and is affected by the number of residents (and related infrastructure) to “absorb” the incoming tourist flows.

Figure 8: Tourists overnight stays per square kilometre in 2001 (Source: GRECO Tourism Sector Study).

Transport

The headline indicator for the transport sector is the motorisation rate (Figure 9). The amount of passenger cars reflects two different aspects of the greening of this sector. On the one hand high motorisation rate indicate often affluent societies that generate high demand for this economic sector. On the other hand, high motorisation rates might also be an indication for the lack of more environmental friendly transport options. Motorisation rates in 'Europe are highest in Italian and Austrian regions and lowest in south-eastern European regions.

Waste management

The headline indicator for the waste sector is the waste recycling ratio. After waste prevention recycling is the most preferred option in the waste hierarchy. Together with industrial ecology it is also the major direction of waste management. As waste prevention is extremely difficult to measure and monitor the level of recycling of different waste streams is the most relevant measure of the regional green performance in the waste sector. Recycling has been increasing through the years but still a small portion of our material consumption comes from recycled material. Depending on the material it is between 3% and 42%. Maximum waste recycling could cover between 6% and 61%. Figure 10 shows the huge differences between European regions in terms of municipal waste recycling rates ranging from almost no recycling at all in some eastern European countries up to recycling rates of almost 80 percent in countries such as the UK, Norway or Germany that have already a long-established waste recycling system.

Water management

The headline indicator for the water sector is the degree of population connected to waste water treatment. Figure 11 shows the percentage of population connected to all types of urban waste water treatment at NUTS 2 level for some countries for which data exists and in the insert for NUTS 0 for a somewhat larger group of countries. In EU-15, the implementation of the Urban Wastewater Directive of the European Union is rather mixed. Significant investments have been made and key infrastructure is in place to a far extent. But there is still a number of agglomerations, for instance in Belgium, France, Greece, Italy and Spain, which completely lack waste water collecting systems and treatment facilities, although progress have been seen in latest years. Against this background it is however important to look at the amount of waste water that undergo at least secondary treatment. More than one third of the European countries for which data is available are connected to secondary waste water treatment.

4. Headline indicators for regional green economic performance for the green economy spheres

This section presents the selected indicators for GREECO's five spheres of the green economy. The presentation is done always at that territorial level at which the data is available.

Environmental sphere

For the environmental sphere, the source function and the sink function are the two main components to be addressed.

The first headline indicator is a comprehensive indicator developed by the EEA on environmental and natural assets, which describes what the current performance of the environment is in terms of availability of open space, biodiversity and other. The indicator is originally been calculated at raster cell level, Figure 12 shows an aggregation to NUTS 3 regions. Regions having the highest environmental and natural assets are located in the northern periphery (Finland, Sweden, Scotland), on islands (Crete, Sardegna, Corsica), in the Alps and in some coastal and non-coastal regions in Spain, Greece and the Baltic States. Regions with lowest assets are mostly the high-density urban agglomerations, their surroundings are mostly classified as second worst category.

The second headline indicator reflects how much the sink function of the environment is being exploited, an indicator of air pollution is used as a proxy for this. Figure 13 displays the density of NO_x emissions per km² which reflects mainly the density of residential and economic activities across Europe. A substantially different spatial pattern emerges if the emission is standardised by population (Figure 14). Now, the high-density areas perform much better, i.e. the emission per person is rather low, whereas rural regions and regions inbetween urban agglomerations have the highest emission rates per population.

Social sphere

For the social sphere, the headline indicator reflect the impact of the economy on the well-being of population; life expectancy is used as a proxy for health. the exposure of population to air pollution as an indication of environmental risks.

Figure 15 presents the life expectancy of males at birth in the year 2010 for NUTS 2 regions in Europe. Life expectancy has many causes, but can also be interpreted as an outcome of the regional health and economic conditions. A regional green economy would enable its population to live longer. However, as the map shows life expectancy is extremely different in European regions. Whereas regions in western Europe offer the highest life expectancy to their population, this dramatically goes down in regions of eastern Europe. Here, in some regions of Bulgaria, Romania or the Baltic States, life expectancy is more than ten years lower than in the best performing regions.

Environmental risks of the population expressed as exposure to air pollution is shown in Figures 16 and 17. The shares of regional population living in areas that exceeded O₃ and PM concentrations are used as demonstration indicators.

Territorial sphere

The concept of territorial keys (Böhme et al. 2011) is used for the territorial sphere. One important territorial key for green economy is "Territorial capacities/endowment assets" for which one of the indicators of the document referred to above can be directly used, i.e. renewable energy production. A second indicator on land take per GDP unit can be seen as a proxy for the "Wise management of cultural and natural assets" or, more generally, as a proxy of "Spatial efficiency".

For Europe, information on renewable energy production is only available at country level (see Figure 18).

The economically efficient use of the territory is expressed as land take, i.e. artificial land use, per GDP (Figure 19). The regional variation ranges from less than 1 ha up to more than 5 ha artificial land per 1 million Euro GDP. High-density urban agglomerations in western Europe have lowest values meaning that relatively little settlement area is being used to produce the economic output. On the other hand, in more rural and peripheral areas in northern, eastern and south-western Europe, the amount of artificial land for the same amount of economic output is much higher, partly up to more than five-times higher.

Economic sphere

For the economic sphere, GREECO's intention was to address the "greenness of economic activities" as far as possible. However, this was almost impossible due to the given data situation in particular in relation to the European Green Goods and Services Statistics (EGGS). However, some indication on greenness of the economy can be made by using national shares of SMEs that offer green products and green services and some indication on regional differentiation in terms of the development of green technologies.

The share of SMEs that offer green products or green services (EC, 2013) varies considerably between countries in Europe (Figure 20). On average, one quarter of the SMEs in Europe has a green component in that respect. Highest shares with about 40 percent of the SMEs are to be found in Austria and Sweden followed by countries such as Slovenia, Slovakia, Germany, the UK and Ireland. Countries in southern Europe and most countries in eastern Europe as well as Finland have low shares of such green market oriented SMEs. Lowest shares of about 10 percent do occur in Hungary and Bulgaria, i.e. about 90 percent of SMEs in those countries do not have any green market orientation.

How far green technology is being developed by the regional economies is reflected in the number of green patents submitted to the European Patent Office (EPO). This indicator can also be considered a green economy driver, as it is strongly related to the green technological development of a given region and thus with its future capacity for green growth. Figure 21 presents the number of green patents submitted in the decade 2001 to 2010. The map shows total numbers by region in order to highlight those areas in Europe with a high concentration of green economic innovation, namely the southern parts of the UK, Belgium and the Netherlands, Denmark and western Germany. There are also strong spatial clusters in northern Italy. Other green patent hotspots are the wider Paris and Lyon regions in France, Madrid and Barcelona, wider Gothenburg and Stockholm regions in Sweden and southern Finland. The number of green patents submitted from Portugal, other regions in Spain and France, from Greece and almost all

eastern European countries is remarkably low. Figure 22 adds the information on the share of green patents of all patents in a region. It can be seen that the high-performing green patent areas are mostly also high-tech areas in general as the share of green patents is not remarkably high. However, some regions having lower numbers of green patents have a higher share in all patents meaning that green research might play a

Econosphere

The econosphere links the environment with the economy. This is usually covered by environmental and resource productivity indicators.

The first headline indicator used here is energy productivity. Figure 23 shows the amount of economic output in terms of GVA being produced per unit of energy consumption. Apart from Norway for which the high energy productivity is based on the oil resources, the most productive areas are the high-density service oriented agglomerations (or countries in the case of Switzerland); Madrid, London, Paris, Rome or Stockholm have highest energy productivity. Less urbanised areas in western Europe, but also most regions in eastern Europe are producing much less economic output per energy unit. The gap between the most and the least efficient regions is enormous.

The second headline indicator is CO₂ productivity (Figure 24). Regions are classified in terms of GDP per CO₂ emission from non-transport territorial fuel combustion. Most efficient regions are located in Norway, Sweden and Switzerland, followed by numerous regions in the UK, France, Germany, Austria and Italy. Usually, regions in eastern Europe are not in a position to produce high economic output per unit of greenhouse gas emissions.

5. Towards a comprehensive typology of regional green economic performance

This section presents the results of the aggregation of the different indicators for the five spheres of the green economy. The objective of the aggregation is to allow some tentative and comprehensive statements about the regional green economic performance and thus allowing for a related typology of regions. The indicators used for this are the headline indicators presented in the previous section. The only indicator not included is the EGSS share as this data does not exist

The aggregation of single indicators into more comprehensive indices is done via techniques of multicriteria analysis. The territorial reference system is NUTS-2 (version 2010). That means that indicators available at NUTS-3 level are aggregated which is depending on the type of indicator done either by simply summing up or by weighted aggregation. For data that does exist only at NUTS-0 or NUTS-1 level, the disaggregation is simply done by using the standardised indicator values also at the lower level, i.e. for reasons of simplicity it is assumed that no spatial variation is existing for that indicator. Data gaps have been estimated by considering neighbouring or other regions which have comparable features. By this, it is guaranteed that all regions have all indicator values, i.e. no bias induced by missing data or indicator does exist.

The indicators are first transformed from their raw values into standardised green performance values which range from 0 to 100. The principle is that the range of raw indicator values should be mapped in a way that the full range of the standardised green performance values is utilised. This means that the green performance values are not oriented at certain objectives but that they should highlight the variety of regional performances. Table 3 shows the indicator system and the indicator raw values that are mapped to the extremes of 0 and 100. The values in between are transformed by a linear function. The table shows also the weights that are used to aggregate from single indicators to the five spheres of the green economy and from there to a comprehensive green performance indicator.

The results of the regional green economic performance for the five spheres of the green economy are presented in Figure 25.

- The performance in the *environmental sphere* shows Nordic and Alpine regions doing best which is an outcome of high environmental and natural assets combined with low emission levels. Similar good is the situation in several coastal regions, the Baltic states and some regions in south-eastern Europe and Spain. Some urban agglomerations, in particular in the UK, Belgium, northern Italy, Poland and Greece do worst, but there are also some more rural regions in Spain and Germany in those lower classes.
- In the *social sphere*, most regions in a broad belt along the Atlantic from Portugal to the Nordic countries are doing fine based on low exposure to air pollution and relatively high life expectancy. Southern European regions suffer from high exposure to air pollution, eastern European regions from very low life expectancy.
- The *territorial sphere* sees Nordic and Alpine regions performing best, a combined result of high renewable energies and high land productivity. German and Italian regions do follow next. Low performance in the territorial sphere is mainly to be found in Eastern Europe, in particular in Bulgaria and Romania, and in some central parts of Spain.

Core feature of Green Economy	Headline indicator definition	Unit	Transformation function	Weights for aggregation to	
				Core feature index	Comprehensive GD index
Environmental sphere	Environmental and natural assets	Classes 1-5	0.5 -> 0 5.5 -> 100	0.5	0.2
	Emission of air pollutants	kg NO _x per inhabitant	<50 -> 0 0 -> 100	0.5	
Social sphere	Life expectancy	years at birth 2010, males	<67 -> 0 >82 -> 100	0.5	0.2
	Exposure to air pollution	% population above O3 health threshold	100 -> 0 0 -> 100	0.25	
	Exposure to air pollution	% population above PM health threshold	100 -> 0 0 -> 100	0.25	
Territorial sphere	Renewable energy production	% of gross inland energy consumption	0 -> 0 >35 -> 100	0.5	0.2
	Land take per GDP unit	ha artificial land per million € of GDP	0 -> 0 >10 -> 100	0.5	
Economic sphere	Green products and services offered	Share of SME that offer green products or services	< 5 -> 0 >45 -> 100	0.5	0.2
	Green patents	Green patents per 1 billion GDP	0 -> 0 >10 -> 100	0.5	
Econosphere	GDP per CO2 unit	1,000 € GDP per ton CO2	0 -> 0 >15 -> 100	0.5	0.2
	GVA per energy unit	€ GVA per kJoule	0 -> 0 >500 -> 100	0.5	

Table 3 Headline indicators used for comprehensive typology of regional green economic performance.

- The *economic sphere* which is only based on the number of green patents per billion GDP sees the largest differences in Europe. Southern Germany, Denmark and some individual regions in Spain, Belgium, the Netherlands, northern Germany, Austria, Sweden and Finland are doing best. In those parts of Europe, the development of green technologies plays a larger role in the regional economy than elsewhere. Then, a large gap exists to most other regions in which the performance is rather low.
- In the *econosphere*, Norway, some UK regions, Stockholm, Madrid and Paris and some individual regions in those countries, regions in southern Germany, Switzerland and Austria, Italy and Denmark are doing best, i.e. having a high economic output per energy unit used. Most regions in Eastern Europe, Finland and Sweden, Spain and good parts of the UK, France and Belgium are at the other end of the spectrum.

The aggregation of the performance of the five spheres to one single regional green economic performance index is presented in Figures 26 and 27. As there is no evaluation of the importance of the different spheres for green economic performance available, the weights assigned are equal, i.e. each core feature contributes 20 percent to the overall performance of a region. The map classes are composed of five quantiles which can be considered as an aggregate typology of regions with respect to regional green economic performance. Regions with high and very high performance are mainly located in the Nordic Countries, Iceland, UK and Ireland, the Netherlands, Germany, Austria and Switzerland and Italy, and also Paris and Madrid. On the other hand, most eastern European regions belong to the type of very low green economic performance because the performance in most of the five different spheres is clearly low.

The diagram in Figure 28 ranks the regions according to their overall green economic performances and decomposes this by the five spheres. The environmental spheres varies a lot in all performance types of regions, i.e. there are good performing regions that have only a moderate environmental performance, but also low performing regions with high environmental performance. The main differences between top and poor performing regions can be found in the economic sphere and in the econosphere. Low performing regions do not have green innovation capacity and at the same time the energy productivity is rather poor. Remarkably, that some of the best performing regions do have a rather low contribution to their position from the economic sphere, i.e. green innovation is not the base for success.

How does the green economic performance relates to different territorial types of regions? First, Figure 29 presents the five core features of regional green economic performance to the urban-rural typology of DG Regio and ESPON. To do so, the NUTS-2 performance indicator were assigned to the NUTS-3 regions to match the resolution of the territorial typology; eventually the NUTS-3 performance values were aggregated by type using regional population as weight. In total, the green economic performance of urban and intermediate regions is somewhat higher than that of rural regions. However, the differences between territorial types at this aggregate level are relatively small. This indicates that there are very distinct degrees of green economic performances within a certain territorial type of regions.

Regional green economic performance Aggregate typology (quantils)

Figure 27. Typology of regional green economic performance.

Figure 28. Decomposition of the typology of regional green economic performance.

Figure 29. Urban-rural typology and regional economic performance

Using a different classification of regions, differences between regional types are much more pronounced. Figure 30 shows the green economic performance by an economic development typology. This typology groups regions according to their economic performance in less developed regions, transition regions and more developed regions. The typology has been developed by DG Regio in order to classify regions for Structural Funds (ERDF and ESF) eligibility for the period 2014 - 2020. In addition to the three types, Iceland, Norway and Switzerland were grouped into one unit as well. A clear territorial pattern emerges. The degree of green economic performance is closely related to the economic development status of the territorial types. The non-EU group of regions is performing best, followed by the more developed regions. Transition regions are in terms of green economic performance also in-between, the performance of less developed regions is lower except for the environmental sphere. A similar pattern emerges if countries are grouped into old and new member states (Figure 31).

Figure 30. Economic development typology and regional economic performance

Figure 31. Groups of European countries and regional economic performance

6. Regional green economic performance vs. regional economic performance

According to the previous relationship, there seems to be a correspondence between the level of green economic performance and the overall regional economic performance. One might also question whether it does pay for a region to have a good green economic performance? Figure 32 relates the standardised regional green economic performance of the five spheres against GDP per capita. At this level of analysis, the relationship is rather weak for the environmental sphere ($R^2 = 0.08$), much more moderate for the social sphere ($R^2 = 0.47$) and the economic sphere ($R^2 = 0.46$), but fairly good for the territorial sphere ($R^2 = 0.62$) and the ecosphere ($R^2 = 0.64$).

However, the aggregation of the performance of the five core features of the green economy to the single comprehensive typology of regional green economic performance shows a relatively high degree of relationship with the economic output of regions in Europe (Figure 33). The distribution of the regions in the diagram gives a clear message supported by the correlation coefficient ($R^2 = 0.74$): Lagging regions are also low performing in green economic aspects, prosperous regions do display a high degree of green economic performance.

Linking the regional green economic performance to regional unemployment rates (Figure 34), a similar linkage is visible, however, the correlation is somewhat lower. Regions with lower unemployment rates tend to behave better in green economic terms. Lower green economic performance seems to be accompanied by higher unemployment rates.

This relationship between regional green economic performance and overall regional economic performance can be seen from two sides. On the one hand, one might argue that it requires a certain degree of economic output to be able to put also an emphasis on green issues. On the other hand, one might consider that investments in greening the regional economy in a broad sense as understood in GREECO will also help in improvements in overall economic performance of such lagging regions.
